“I know my value”

Achieving high quality anticoagulation management with specialised clinic care
Vitamin K antagonists and monitoring provide patients with highly effective anticoagulation

The growing need for anticoagulation will require more efficient models of care

Warfarin and monitoring are used to manage several diseases

The vitamin K antagonist (VKA) warfarin is the most commonly used oral anticoagulant (OAC) in clinical practice. It is frequently used to reduce the risk of stroke in patients with atrial fibrillation (AF) and also to treat or prevent venous thromboembolism (VTE). In addition, patients who have received a mechanical heart valve (MHV) currently require lifelong treatment with warfarin.

Warfarin is a highly effective oral anticoagulant, offering significant improvements over placebo or antiplatelet agents. Regular monitoring of the International Normalized Ratio (INR) ensures therapeutic efficacy and reduces the risk of bleeding complications. In addition to ensuring clinical effectiveness, monitoring also provides a means of assessing patient adherence, general health and the opportunity to address patient questions regarding their anticoagulation treatment.

The demand for anticoagulation care is rising

Millions of people worldwide are already taking OACs. This number will continue to rise due to the population ageing and the growing prevalence of conditions which predispose to thromboembolic events. In particular, AF is already being described as an epidemic. In 2010, AF was estimated to have affected around 5.2 million people in the US (projected to 12.1 million in 2030) and around 8.8 million in the EU (projected to 12.9 million in 2030).

Until recently, many patients, particularly the elderly and Asian patients, have been undertreated with warfarin due to concerns about bleeding complications. However, there is now a growing awareness that, even in high-risk patients, the benefit of stroke reduction outweighs the risk of bleeding associated with warfarin therapy.

The rising number of patients on OACs will automatically lead to an increased demand for anticoagulation care. In addition, as patients get older, they are more likely to be treated with multiple other drugs and to be affected by cognitive impairment and may become more forgetful. Consequently, it has been suggested that elderly patients may require more frequent monitoring.

To meet the rise in demand, healthcare providers will need to develop efficient models of anticoagulation care.

Regular monitoring of the International Normalized Ratio (INR) ensures therapeutic efficacy and reduces the risk of bleeding complications. In addition to ensuring clinical effectiveness, monitoring also provides a means of assessing patient adherence, general health and the opportunity to address patient questions regarding their anticoagulation treatment.

The demand for anticoagulation care is rising. Millions of people worldwide are already taking OACs. This number will continue to rise due to the population ageing and the growing prevalence of conditions which predispose to thromboembolic events. Until recently, many patients, particularly the elderly and Asian patients, have been undertreated with warfarin due to concerns about bleeding complications. However, there is now a growing awareness that, even in high-risk patients, the benefit of stroke reduction outweighs the risk of bleeding associated with warfarin therapy.

The rising number of patients on OACs will automatically lead to an increased demand for anticoagulation care. In addition, as patients get older, they are more likely to be treated with multiple other drugs and to be affected by cognitive impairment and may become more forgetful. Consequently, it has been suggested that elderly patients may require more frequent monitoring.

To meet the rise in demand, healthcare providers will need to develop efficient models of anticoagulation care.
Effective anticoagulant management is critical for achieving good clinical outcomes for warfarin patients and for making optimal use of the financial and human resources available within the local healthcare system. In addition, healthcare providers are increasingly aware of the need to develop management systems which offer improved convenience and flexibility for the patient.

The three main models of care that are currently used in clinical practice are (1) usual care, (2) alternative site testing (AST), and (3) patient self-monitoring.

**Usual care**
- Many patients taking warfarin are monitored by a hospital physician or general practitioner (GP) in a traditional model referred to as usual care (Fig. 1)
- Typically patients attend appointments at their GP’s surgery or local hospital. At each appointment a venous blood sample is drawn and sent to a centralised laboratory for INR testing
- Once the result is available, the patient is contacted and advised of any warfarin dose adjustments
- Studies that describe usual care have often reported that no specific standardised protocol of care is used by primary care physicians, and in some instances no dosing algorithm is used; instead, individual physician knowledge and experience is utilised
- In addition, GPs and hospital clinics may have little time or few resources available for educating patients on anticoagulation safety

---

**Choosing the right model of care for your patients**

*Point-of-care testing models have simpler and more effective workflows than usual care*

Fig. 1: Workflow in the usual care model
Effective anticoagulant management is critical for achieving good clinical outcomes for warfarin patients and for making optimal use of the financial and human resources available within the local healthcare system. In addition, healthcare providers are increasingly aware of the need to develop management systems which offer improved convenience and flexibility for the patient.

The three main models of care that are currently used in clinical practice are (1) usual care, (2) alternative site testing (AST), and (3) patient self-monitoring.

**Usual care**
- Many patients taking warfarin are monitored by a hospital physician or general practitioner (GP) in a traditional model referred to as usual care (Fig. 1).
- Typically patients attend appointments at their GP's surgery or local hospital. At each appointment a venous blood sample is drawn and sent to a centralised laboratory for INR testing.
- Once the result is available, the patient is contacted and advised of any warfarin dose adjustments.
- Studies that describe usual care have often reported that no specific standardised protocol of care is used by primary care physicians, and in some instances no dosing algorithm is used; instead, individual physician knowledge and experience is utilised.
- In addition, GPs and hospital clinics may have little time or few resources available for educating patients on anticoagulation safety.

**Choosing the right model of care for your patients**
- Point-of-care testing models have simpler and more effective workflows than usual care.

**Alternative site testing (AST)**
- Increasing evidence shows that better outcomes can be achieved if patients are managed by a specialised anticoagulation management service.
- Specialised management can occur at sites separate from the patient’s GP or hospital outpatient clinic and is therefore often called alternative site testing (AST) (Fig. 2).
- The most common of these alternative sites is the anticoagulation (AC) clinic.
- The role of an AC clinic is to provide consistent, systematic and protocol-driven care and recommendations have been published which recommend that this is achieved by using standardised protocols, dosing algorithms, extensive patient education and a systematic approach to patient tracking.
- In addition, AC clinics may perform near-patient testing point-of-care (POC) INR devices in order to streamline the clinic workflow.
- Many AC clinics are run by pharmacists or nurses and the use of computerised decision support systems (CDSS) can reduce reliance on physician delivery of oral anticoagulant therapy.

**Patient self-monitoring**
- Due to the availability of POC INR meters, testing can be easily transferred to the patient, thereby reducing the pressure on busy AC clinics.
- In the patient self-testing (PST) model (Fig. 3), patients have their own meter and perform an INR test at a time convenient to them. They report the result to their health care professional and are provided with instructions on dose adjustment.
- Alternatively patients can also learn to adjust their own dose, in a model referred to as patient self-management (PSM).
AST improves clinical outcomes

Increasing patients’ safety and quality of life

Staying longer in INR therapeutic range is the key to success

Determination of the time in therapeutic range (TTR) is the most recognised way to measure the therapeutic effectiveness of warfarin management over time and has been shown to correlate strongly with clinical outcomes (Fig. 4).\(^{23,24}\) Many studies have now established that the structured care found in AC clinics can improve TTR and produce better clinical outcomes than those which are achieved with usual care.\(^{15,21,25,26}\)

- AST increases the amount of time or the number of INR results that are within the therapeutic range. This has been demonstrated in a number of settings in both developed and developing countries (Fig. 5)\(^{15,16,21}\)
- AST reduces the rate of complications. A review of available studies in which care was managed by an anticoagulation management service indicated a 59% reduction in major hemorrhagic events and a 68% reduction in thrombotic events (Fig. 6)\(^{25}\)
- AST reduces the rate of hospitalisations. Two separate studies found that usual care patients were 2.6 times\(^{21}\) and 4.2\(^{26}\) times more likely to be hospitalised for warfarin-related complications than AST patients

**AST results in better clinical outcomes due to a combination of:**

- **Shorter time periods between INR tests.** In one study, AC clinic patients had significantly fewer INR tests drawn more than 6 weeks apart than the usual care group (3.7% vs 8.1%)\(^{26}\)
- **Enhanced patient education.** The intensive education provided by AC clinics may improve warfarin adherence and alert patients to the potential of drug-drug and drug-food interactions\(^2\)
- **Specialised AC clinic staff.** Staff in AC clinics will have received specialist training regarding warfarin therapy\(^{27}\)
- **Provides real time results.** Dose adjustment is based on a current result rather than one which may be one to two days out of date\(^{15}\)
- **Use of dosing algorithms or computerised decision support system (CDSS).** Several studies have demonstrated that CDSS can increase TTR and improve clinical outcomes.\(^2\) It enables non-attending patients to be quickly identified and contacted,\(^{21}\) and there is less chance that patients can be lost to follow-up\(^2\)
Staying longer in INR therapeutic range is the key to success. Determination of the time in therapeutic range (TTR) is the most recognised way to measure the therapeutic effectiveness of warfarin management over time and has been shown to correlate strongly with clinical outcomes (Fig. 4). Many studies have now established that the structured care found in AC clinics can improve TTR and produce better clinical outcomes than those which are achieved with usual care.

- AST increases the amount of time or the number of INR results that are within the therapeutic range. This has been demonstrated in a number of settings in both developed and developing countries (Fig. 5).

- AST reduces the rate of complications. A review of available studies in which care was managed by an anticoagulation management service indicated a 59% reduction in major hemorrhagic events and a 68% reduction in thrombotic events (Fig. 6).

- AST reduces the rate of hospitalisations. Two separate studies found that usual care patients were 2.6 and 4.2 times more likely to be hospitalised for warfarin-related complications than AST patients.

AST results in better clinical outcomes due to a combination of:

- Shorter time periods between INR tests. In one study, AC clinic patients had significantly fewer INR tests drawn more than 6 weeks apart than the usual care group (3.7% vs 8.1%).

- Enhanced patient education. The intensive education provided by AC clinics may improve warfarin adherence and alert patients to the potential of drug-drug and drug-food interactions.

- Specialised AC clinic staff. Staff in AC clinics will have received specialist training regarding warfarin therapy.

- Provides real time results. Dose adjustment is based on a current result rather than one which may be one to two days out of date.

- Use of dosing algorithms or computerised decision support system (CDSS). Several studies have demonstrated that CDSS can increase TTR and improve clinical outcomes.

Many studies have now established that the structured care found in AC clinics can improve TTR and produce better clinical outcomes than those which are achieved with usual care.
AC clinics which utilise point-of-care testing and CDSS can develop a streamlined approach to managing patient care, whereas the usual care model is generally quite time-consuming for both patient and health care professional.

- **Fewer consultations.** In AST, INR testing and dose adjustment can be achieved in a single visit. For usual care, two consultations are typically required.15
- **Less retrieval of clinical records.** In AST, administrative staff only need to obtain a patient's clinical records once, whereas for usual care, clinical records are often obtained on at least two separate occasions.15
- **Dose adjustment ‘on the spot’**. In AST, the patient is usually given their dose adjustment recommendation before they leave their appointment. In the usual care model, the physician or physician’s representative must contact the patient to provide them with dose-adjustment guidance. This can be particularly time-consuming if multiple attempts are required before the patient is reached.15
- **Lower risk of errors.** With AST, near-patient testing reduces the risk of laboratory or communication errors. With usual care, blood samples can be lost during delivery to the laboratory or there may be communication errors which prevent the sample being analysed or the result being conveyed back to the physician. This may require the patient to re-attend for another blood draw.15
- **More physician time available for other tasks.** In AST, routine visits can be handled by nurses or pharmacists, freeing up physician time for other work. With usual care, physicians monitor all patients regardless of the complexity of the case.15
AST is more cost-effective than usual care
Lowering costs and increasing financial revenue

A number of studies have demonstrated that AC clinics are generally more cost-effective than usual care as they can reduce overall costs and in some cases generate revenue for the healthcare provider.

- **Lower staff costs.** AC clinics tend to have lower staffing costs as they are usually run by nurses or pharmacists, who cost less to employ than physicians.\(^{29}\) In addition, administrative costs are also lower due to improved workflow efficiency.\(^{15}\)
- **Lower hospitalisation costs.** Reduced hospitalisation rates achieved with AC clinic care can lead to cost savings of approximately US dollars 1,000 per patient-year of therapy.\(^{25}\)
- **Increased revenue.** In many countries, warfarin monitoring by usual care does not generate revenue as physicians are not specifically reimbursed for providing this service, especially if they are only providing a telephone consultation.\(^{29,30}\) In contrast, in some countries, specialised AC clinics can attract additional funding which can be a source of revenue for the healthcare provider (Fig. 7).\(^{15,31}\)

![Fig. 7: The use of POC devices in AC clinics can generate revenues and reduce costs (based on Medicare minimum allowable charges and assuming an average of two visits per patient per month).](image-url)
Overall, patient satisfaction is higher if patients are cared for by AC clinics compared with the usual care model.

- Patients prefer capillary sampling to venous sampling as it is perceived to be less painful.
- A number of studies comparing usual care with AST have assessed patient satisfaction and have concluded that patients prefer to be cared for in an AC clinic (Fig. 8) and.
- Patients who returned to usual care after being in an AC clinic were less satisfied than patients who remained in an AC clinic.
AST can help to meet the rising demand for anticoagulation care

An efficient and highly effective model of care

To meet the rise in demand, healthcare providers will need to develop efficient models of anticoagulation care. Dedicated AC clinics offer improved workflow efficiency and can be more cost-effective than usual care.\textsuperscript{15,25,28} In addition, the use of dosing algorithms or CDSS enables nurses and pharmacists to directly manage patients,\textsuperscript{7} therefore reducing the burden on physicians. Consequently, AC clinics may prove to be a highly effective option as the number of patients requiring oral anticoagulation continues to increase.

\textbf{Take-home messages:}
- Worldwide, the prevalence of conditions with an indication for OACs is growing\textsuperscript{7,12}
- To meet this rise in demand, healthcare providers need to develop efficient models of anticoagulation management
- Dedicated AC clinics offering structured and protocol-driven care can improve clinical outcomes and be more cost-effective than usual care models\textsuperscript{25}
- AC clinics can be managed by specialised pharmacists or nurses, reducing the burden on physicians\textsuperscript{2}
- Performing POC INR tests within an AC clinic saves time and is preferred by patients\textsuperscript{32}
